A modified *Kaprekar number* is a positive whole number n with d digits, such that when we split its square into two pieces - a right hand piece r with d digits and a left hand piece l that contains the remaining d or $d - 1$ digits, the sum of the pieces is equal to the original number (i.e. $l + r = n$).

Note: r may have leading zeros.

Here's an explanation from Wikipedia about the **ORIGINAL** Kaprekar Number (spot the difference!); *In mathematics, a Kaprekar number for a given base is a non-negative integer, the representation of whose square in that base can be split into two parts that add up to the original number again. For instance, 45 is a Kaprekar number, because $45^2 = 2025$ and $20+25 = 45$.*

The Task

You are given the two positive integers p and q , where p is lower than q . Write a program to determine how many Kaprekar numbers are there in the range between p and q (both inclusive) and display them all.

Input Format

There will be two lines of input: p , lowest value q , highest value

Constraints:

$$0 < p < q < 100000$$

Output Format

Output each Kaprekar number in the given range, space-separated on a single line. If no Kaprekar numbers exist in the given range, print *INVALID RANGE*.

Sample Input

```
1
100
```

Sample Output

```
1 9 45 55 99
```

Explanation

1, 9, 45, 55, and 99 are the Kaprekar Numbers in the given range.
